1. Introduction

The development phase is the process of converting the requirements and system design into a working Access Control system. In this project, the system is developed to control user access based on their roles, ACL permissions, and branch conditions or scripts. The main purpose of development is to ensure that only authorized users can access the required resources.

2. Development Objectives:

The main objectives of the development phase are:

- To implement the identified project requirements.
- To create and configure user roles.
- To implement Access Control Lists (ACLs).
- To apply appropriate permissions to resources.
- To implement branch conditions and scripts.
- To provide access based on authorization rules.
- To prevent unauthorized access.
- To integrate all components into a single system.

3. User Role Implementation:

User roles are implemented to identify the level of access given to each user. Different users may have different permissions depending on their assigned role.

For example:

- Administrator – Can manage users and system resources.
- Manager – Can access resources assigned to the manager.
- Normal User – Can access only permitted resources.

The role of the user is checked before granting access to protected resources.

4. ACL Implementation:

Access Control Lists are implemented to define who can access a particular resource and what actions they are allowed to perform. The ACL checks the user's role and permissions before allowing access.

The basic process is:

User Request → Check Role → Check ACL → Check Conditions → Allow/Deny Access

5. Branch Conditions and Scripts:

Branch conditions or scripts are used for additional access verification. They check whether specific conditions are satisfied before granting permission. If the required conditions are satisfied, the system continues with the access process. If the conditions fail, access is denied.

6. Access Decision:

After all required checks are completed, the system makes the final access decision.

- If the user is authorized → Access Granted

- If the user is not authorized → Access Denied

This ensures that restricted resources are protected from unauthorized users.

7. System Integration:

The implemented modules are integrated to create a complete Access Control system. User roles, ACLs, conditions, and access decisions work together to provide controlled access.

8. Conclusion

The development phase converts the project requirements and design into a functional Access Control system. The implemented system provides controlled access based on user roles, ACL permissions, and defined conditions.
